

Another troughing pattern will move through the northern half of California this weekend, bringing wetter weather for a brief period of time. CPC maps are still showing near to above average precipitation anomalies over California for the month of March, but both the Euro and GFS have begun to trend drier heading towards April. Extended forecasts support this trend as high pressure ridging looks to arrive some time next week. Both CPC and the European model show temperature trends leaning towards near to above average in response to expected ridging. Heading into the latter half of Spring, models show precipitation chances will be near seasonally average throughout all of California. Models do show some agreeance for temperature trends through May, with increasing chances for above average temperatures will be expected. This could be indicative of high pressure taking on a more prominent role in the weather pattern for the state in the months to come.
